

Prosociality increases in harsh and unpredictable environments

Introduction

Environmental characteristics affect people's survival and reproductive success. Under conditions of environmental harshness and limited resources, prosociality and cooperation are generally needed to survive and reproduce successfully. There is a broad consensus that people adopt a faster life-history strategy by focusing on short-term outcomes in such environments, but it is unclear how prosociality varies with ecological environments.

Method

We carried out a nationwide survey in China (Study 1; N = 22,652; 49.25% females; age range = 17–97 years) and used World Value Survey (WVS) data from 57 countries (Study 2; N = 79,619; 51.74% females; age range = 16–99 years).

We used the Human Development Index (HDI) as an indicator for the ecological environments of different areas. Different measures were used to assess the level of prosociality:

<u>Study 1.</u> Prosociality was measured by the dictator game: Participants were asked to propose a division of ¥100 between self and an anonymous person.

<u>Study 2.</u> Prosociality was measured using two items in the WVS : 1) It is important to do something for the good of society and 2) It is important to looking after environment, care for nature and save life resources.

We estimated the effects of HDI and demographic variables on prosociality using mixed-effects linear regression in R.

Results

We consistently found that HDI is negatively associated with prosociality after controlling for the demographic variables. Namely, individuals living in harsher and more unpredictable environments displayed greater prosociality.

Table 1. Estimated fixed-effects coefficients from the mixed-effects regression models of prosocial behavior across 31 provinces in China We also consistently found that HDI for each country/area is significantly associated with an age effect: Higher HDI is associated with a greater age effect and thus with bigger differences between younger and older age groups.

specific age-effect estimates obtained from the mixedeffects regression model without HDI as a predictor

Conclusion

Our work supports the possibility that harsh and unpredictable environments promote prosociality while contradicting expectations from life-history theory that harsh environments inhibit prosociality.

Our findings shed light on the effects of living in a harsh, unpredictable environment and the origin of prosocial behavior.
