

### Introduction

• The most widely applied **non-expected utility theories**<sup>1,2,3</sup> combine the classical core of expected utility theory<sup>4</sup> with a concave utility function and non-linear probability weighting to account for findings unexplained by EUT<sup>5,6,7</sup>

$$EV(X) = \sum_{i=1}^{n} \pi(p_i) * \nu($$

- the estimated shape of these functions remain unclear sampling<sup>8</sup>, efficient coding<sup>9, 10, 11</sup>, heuristic processing<sup>12</sup> or attentional processes<sup>13, 14</sup>, whereas probability weighting has been suggested to result from sensitivity to extreme probabilities<sup>1, 15</sup>, a log-odds
- Despite of decades of research, the psychological processes underlying • Earlier work has suggested that **concave utility** could reflect **decision by representation** of frequency and probability-related information<sup>16</sup>, and/or bounded rationality<sup>17, 18</sup>
- Based on existing work in perceptual and cognitive psychology<sup>19, 20, 21, 22</sup> and neuroscience<sup>23, 24</sup>, the present approach builds on the assumption that areduction in uncertainty carries utility

## Valence-Weighted Distance (VWD)

- The perception of a probability *p* is influenced by the amount of uncertainty reduction it carries
  - relative to the **uniform** distribution (maximum entropy)
  - depending on other probabilities in the distribution (actual entropy)
- Formally:

$$VWD(p) = \frac{p^{\left(1 - \frac{H_{dist}}{H_{max}}\right)}}{\sum_{i=1}^{n} p_i^{\left(1 - \frac{H_{dis}}{H_{max}}\right)}}$$

where  $Hdist = -\sum p_i \log_2(p_i)^{26}$ ,  $Hmax = \log_2(n)$ , and *n* denotes the number of probabilities in the distribution that p is embedded in

• This yields an *n*-dimensional function that has its fixed point at 1/n and curvature that depends on the entropy of the distribution

Note: Existing probability weighting functions cannot reflect changes in n or distributional shape without changes in fitted parameters

# Information Theory Meets Expected Utility: The Entropic Roots of Probability Weighting Functions

### Mikaela Akrenius, Indiana University Bloomington

### $x_i$

**Figure 2.** VWD(p) when *n* is varied from to 2 to 7 while retaining maximum entropy (left) and when entropy is varied while n = 3 (right)

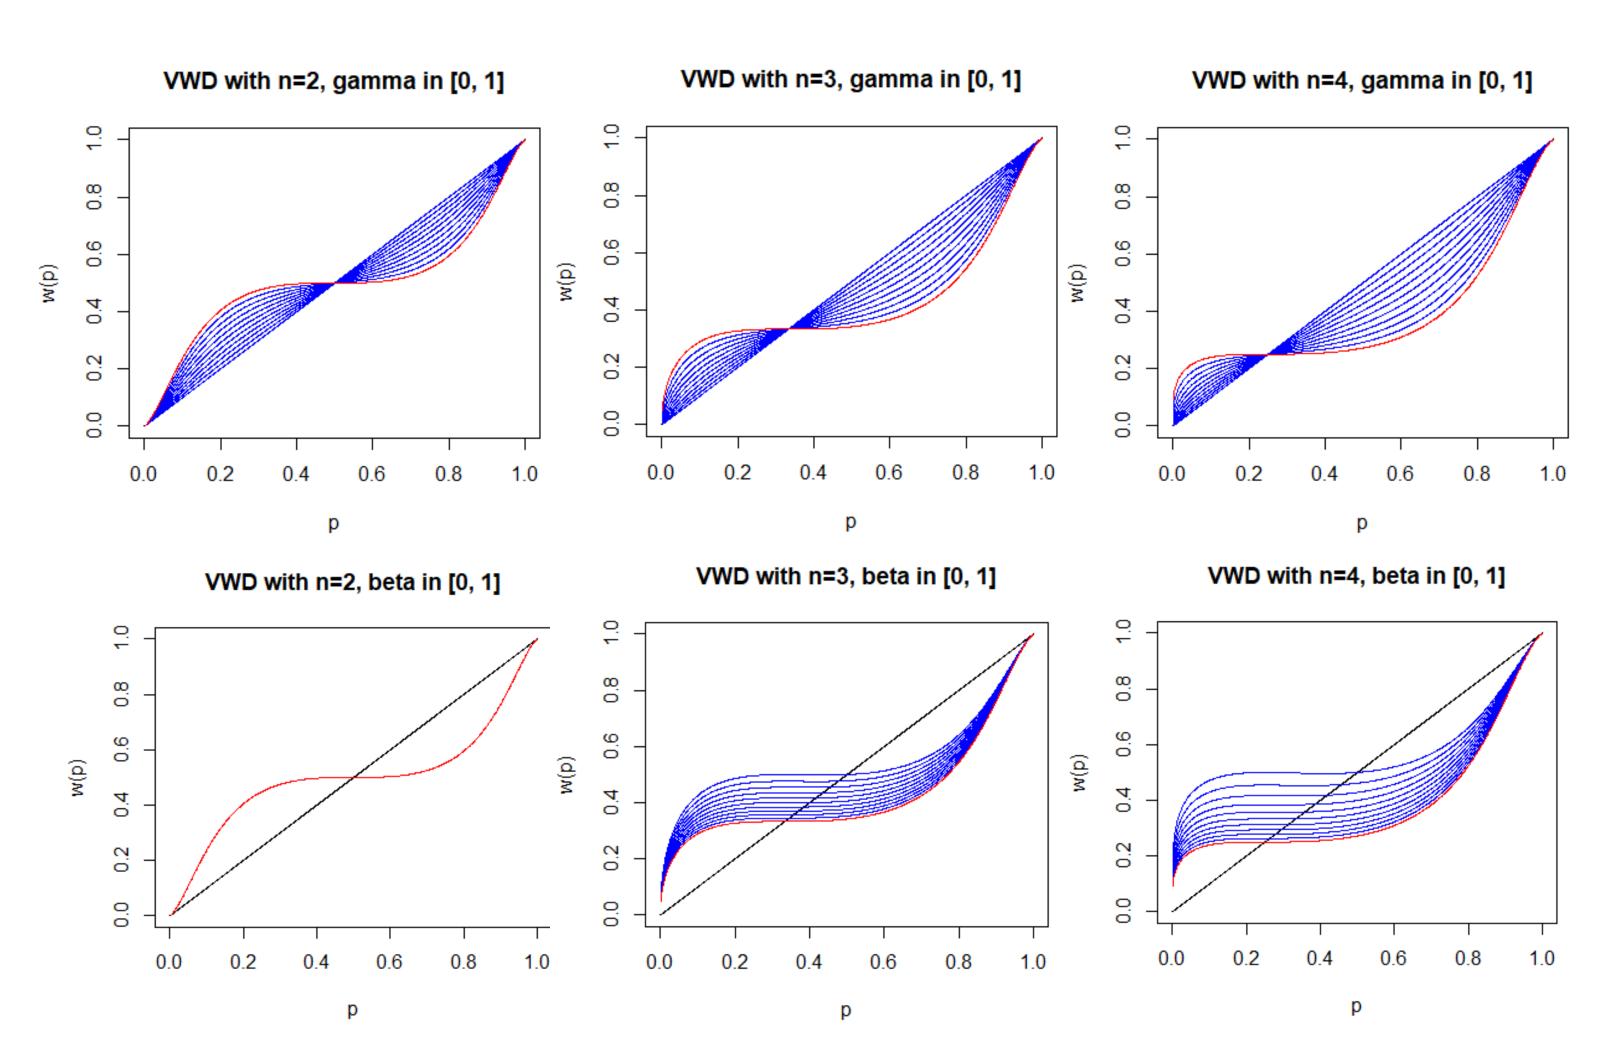

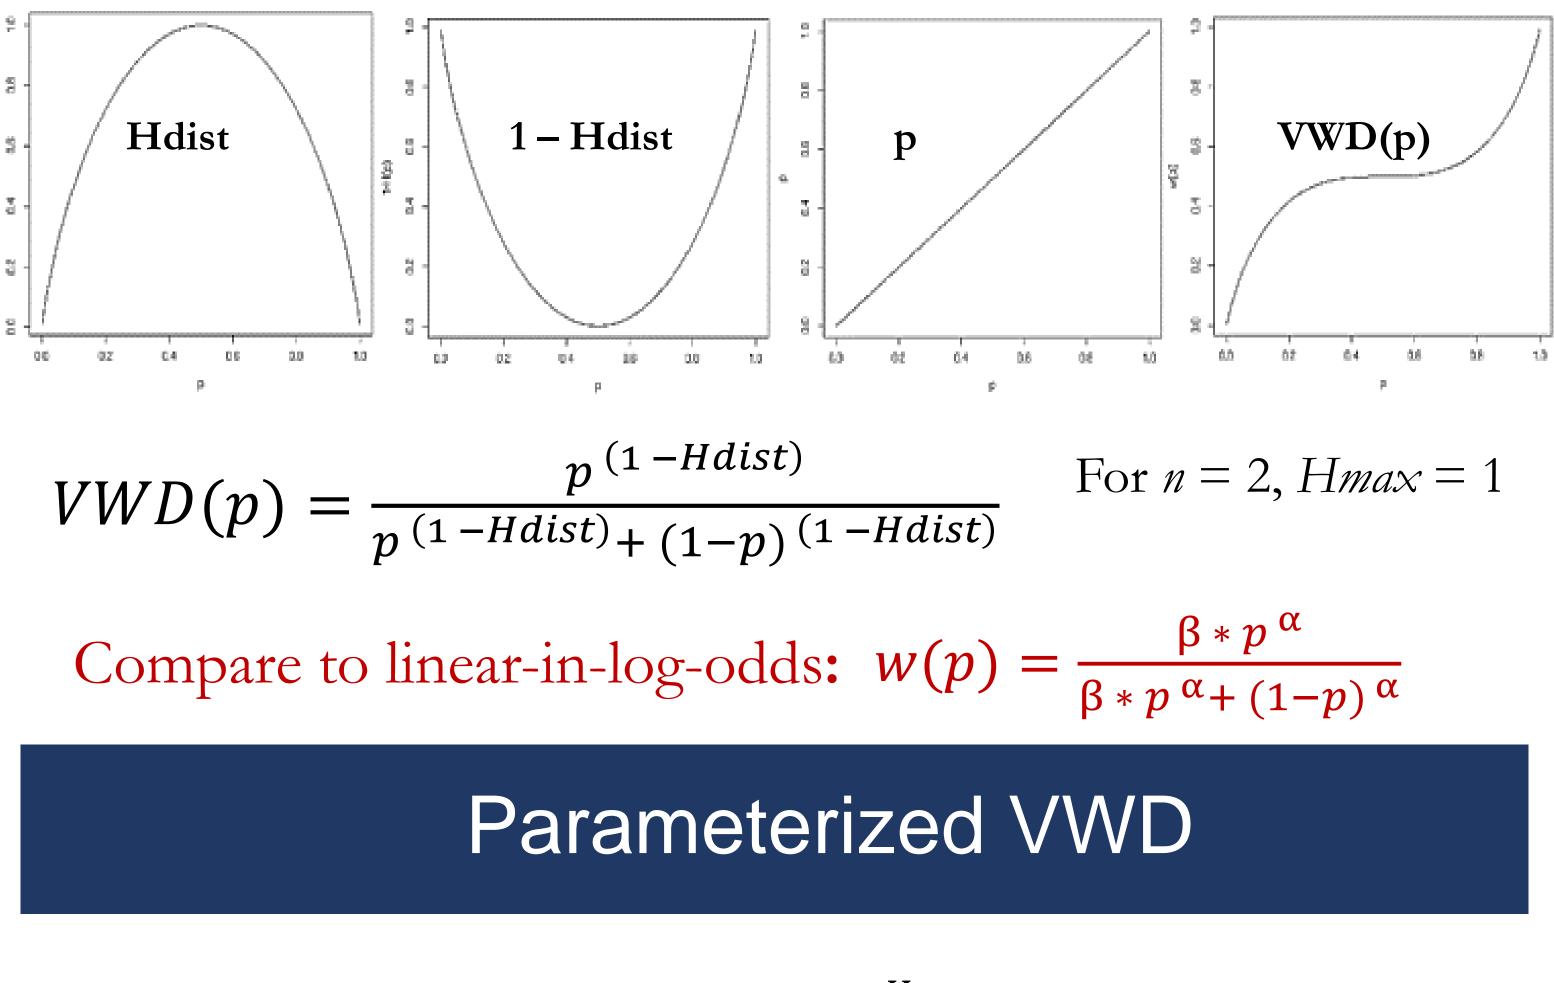

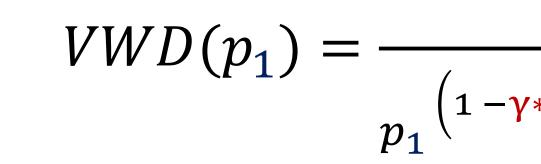

Figure 1. Existing probability weighting functions<sup>3, 27, 28, 29, 30</sup>

Hdist

**Figure 3.** Parameterized VWD(p) when  $\gamma$  is varied from 0 to 1 while fixing  $\beta$  to 1 (upper row) and when  $\beta$  is varied from to 0 to 1 while fixing  $\gamma$  to 1 (lower row) for n = 2 (left), n = 3 (middle), and n = 4 (right).

- Provides a parsimonious explanation for the 1/n puzzle<sup>16</sup>

 $log_{\frac{1}{1}}$ 

## Illustration with n = 2

Utility of uncertainty reduction merged with utility of increased likelihood of gain

$$p_{1}\left(1-\gamma*\frac{Hdist}{Hmax}\right)$$

$$\cdot\gamma*\frac{Hdist}{Hmax}+\beta*\sum_{i=2}^{n}p_{i}^{\left(1-\gamma*\frac{Hdist}{Hmax}\right)}+(1-\beta)*(1-p_{1})\left(1-\gamma*\frac{Hdist}{Hmax}\right)$$

where  $\beta$ ,  $\gamma \in [0, 1]$  reflect attention given to *n* and entropy

### Contributions

### 1. Probability weighting

• Explains probability weighting with a simple principle • Takes context of p(n, shape of distribution) into account • Makes novel, empirically testable predictions • Location of fixed point determined by *n* • Curvature determined by shape of distribution 2. Expected utility theory and information theory • Captures the psychological impact of **outcome**probability associations<sup>31</sup> cf. <sup>32, 33</sup> 3. Log-odds representation of frequency and probability

$$\frac{VWD(p_i)}{1 - VWD(p_i)} = \log \frac{p_i \left(1 - \frac{H_{dist}}{H_{max}}\right)}{\sum_{j=1}^n p_j \left(1 - \frac{H_{dist}}{H_{max}}\right)} \quad \text{where } i \neq j$$
